- T' is an **extension** of T if $T' \vDash A$ for all $A \in T$ (T' can prove new facts about formulas of \mathcal{L}_T)
- T' is a **conservative extension of** T if for all $A \in \mathcal{L}_T$ from $T' \vDash A$ we get $T \vDash A$ (T' **cannot** prove new facts about formulas of \mathcal{L}_T but it can about formulas of $\mathcal{L}_{T'}$),
- Special case of conservative extensions are **extensions by definitions** where **no** new facts about formulas of $\mathcal{L}_{T'}$ can be proved because every theorem of T' can be **translated** to an equivalent theorem of T .

Peano
Arithmetic

- For arbitrary **theory** T we have learnt to prove **theorems** A of **extensions** T' as **logical consequences**: $T' \vDash A$,
- we will now study a particular theory **Peano arithmetic** (PA)
- our **goal** is to show that the **clauses** of legal **CL** definitions are theorems in **definitional extensions** of PA
- Thus all properties of CL programs are provable in PA but the extensions make for **readability** and for the **computability** directly from the clauses

The **language of PA** consists of the **constant** 0 and **function symbols** x' , $x + y$, $x \cdot y$.

The **standard structure** \mathcal{N} has the domain \mathbb{N} of natural numbers with the intended interpretation of symbols in that order as **zero**, **successor**, **addition**, and **multiplication** functions.

The **axioms of PA** are

$$x' \neq 0 \qquad x' = y' \rightarrow x = y$$

$$0 + y = y \qquad x' + y = (x + y)'$$

$$0 \cdot y = 0 \qquad x' \cdot y = (x \cdot y) + y$$

$$A[0, \vec{y}] \wedge \forall x (A[x, \vec{y}] \rightarrow A[x', \vec{y}]) \rightarrow A[x, \vec{y}]$$

for **all** formulas $A[x, \vec{y}]$ of the language of PA. The last axioms are called the axioms of **mathematical induction** with x called the **induction** variable and \vec{y} (if any) the **parameters**

Incompleteness of PA: Goodstein's sequence

theories

Peano
Arithmetic

For $x > 0$ write the number $x - 1$ **fully** in **base** $n \geq 2$. For instance, for $x = 528$ and $n = 2$:

$$x = 528 = 2^9 + 2^4 + 1 = 2^{2^3+1} + 2^{2^2} = 2^{2^{2^1+1}} + 2^{2^{2^1}}$$

$x = 527 = 2^{2^{2^1+1}} + 2^{2^1+1} + 2^{2^1} + 2^1 + 1$ and **change** to base $n + 1 = 3$:

$$P_n(x) = 3^{3^{3^1+1}} + 3^{3^1+1} + 3^{3^1} + 3^1 + 1.$$

Subtract one and change to base 4, obtain $P_{n+1}(P_n(x))$, and continue. This is called **Goodstein's sequence**

There is a formula $A[n, x]$ of PA which says **Goodstein's sequence for $n \geq 2$ and any x terminates in finitely many steps in 0**

We have $\models^{\mathcal{N}} \forall n \forall x A[n, x]$ **but** $\text{PA} \not\models \forall n \forall x A[n, x]$.

Hence by **Gödel's completeness** there is a **non-standard** structure \mathcal{M} for natural numbers s.t. $\models^{\mathcal{M}} \text{PA} + \neg \forall n \forall x A[n, x]$.

Peano
Arithmetic

To every **consistent** extension T of PA in the same language there is a sentence A of PA such that $\models^{\mathcal{N}} T + A$ but neither $T \vdash A$ nor $T \vdash \neg A$.

Thus **arithmetic** is **essentially incomplete**, i.e. to every such T there is a **non-standard model of arithmetic** \mathcal{M} such that $\models^{\mathcal{M}} T + \neg A$.
